

Manager + Operator Training

Your warehouse experience, connected
through one shared system

1 min

By the end, the system should feel familiar

YOUR WORK

The pallet journey you already manage

ONE SHARED MEMORY

Scans and updates everyone can see

GOOD JUDGMENT

Pause when the floor and screen disagree

CLEAR HANDOFFS

The next person knows what happened

The system follows the same questions you already ask

**WHAT IS IT? → WHERE IS IT? → WHAT
HAPPENED? → WHO NEEDS TO KNOW?**

The scan gives the team a shared answer without replacing the walk-around, count, or conversation.

The work stays familiar—the handoff becomes visible

A good shift starts the way it always has

MANAGER — 5 TO 10 MIN

- Choose warehouse + Dashboard view
- Review open work and staffing
- Check holds, quarantine, space, RF alerts
- Assign owners; release finishable work

OPERATOR — 2 TO 5 MIN

- Sign in; verify active warehouse
- Check scanner, network, battery, printer
- Confirm PPE + equipment
- Read priority; open assigned queue

The system supports the walk-around: people, space, stock, equipment, and priority still have to agree.

Every pallet already has a story—the system keeps it together

Counts, moves, status controls, and audit protect the journey at every stage.

Receiving: scan → commit → count → expiry

1	CONTEXT	Warehouse · container · PO
2	PRODUCT	Scan/search, then press the right-arrow
3	QUANTITY	Total → qty/pallet → pallets
4	TRACE	Expiry · lot · batch · packaging
5	RECEIVE	Verify once · print labels · create Put-Away

The physical count always wins. A learned suggestion never replaces the count.

Put-Away: two scans, every pallet, every time

01 PALLET

Who/what is moving?

02 EXACT LOCATION

Where did it physically go?

- A bay code opens the grid; it is not the final cell
- Check physical capacity, safety, and temperature
- Confirm once, then verify the task cleared

STOP: inactive, full, blocked, unsafe, or temperature-incompatible cell.

Inventory Search is the truth check

Use it before substitution, correction, status change, transfer, or variance resolution.

Manager gate: release only work the floor can finish

Shortfall or split required? Replan before release.

Pick Execution: location first, pallet second

- 1 TRAVEL** Read rack · aisle · bay · level
- 2 LOCATION** Scan exact cell or select assigned bay cell
- 3 PALLET** Verify condition + whole quantity; scan
- 4 CONFIRM** Use the highlighted Confirm pick
- 5 STAGE** Move to directed outbound lane

One pallet = one task. Confirm the whole assigned pallet or stop.

When something looks wrong, pause before it becomes tomorrow's problem

1. KEEP THE PALLET SAFE
2. CHECK PALLET · LOCATION · TASK
3. LOOK UP THE LIVE RECORD
4. AGREE THE NEXT ACTION
5. CONTINUE ONCE THE STORY MATCHES

TRIGGERS

- Short quantity
- Missing pallet
- Damage / contamination
- Unknown barcode
- Full or blocked cell
- Offline device

Move or Transfer? Let the warehouse boundary decide

LOCATION MOVE

- Same warehouse
- Scan pallet + exact destination
- Preserves identity + movement history
- Cancel queued/in-progress move if plan changes

TRANSFER

- Different warehouse
- Create → stage → driver sign-off
- In-transit → destination receive
- Immediate directed Put-Away

Never strand transferred stock in a receiving lane while the system implies it is stored.

Cycle Counts: count what you see, then learn from the variance

A variance points upstream: receiving, put-away, movement, pick, transfer, label, or status.

Offline means freeze the commit — not invent a workaround

1

SIGNAL LOST

Keep the pallet in its current safe state

2

DO NOT REPEAT

No forced save, receive, move, pick, or approval

3

RECONNECT

Confirm backend connection is restored

4

REFRESH + RECHECK Task · pallet · location · quantity · status

5

POST ONCE

Verify completion from live state

Controlled status makes restricted stock visible

HOLD	Review needed; disposition unknown
QUARANTINE	Quality / expiry / contamination / temperature
DAMAGED	Verified physical damage
MISSING	Verified search/count supports it
AVAILABLE	Authorized and verified for normal work

Every change needs a reason. Add a System Log owner when follow-up is required.

The dashboard backs up the walk-around—it does not replace it

START

Open work · people · space
· RF

MID-SHIFT

Backlog · staging · holds ·
expiry

END

Floor vs queues · owners ·
safe handoff

Where is work accumulating?

What is blocked?

Who owns it?

When is it due?

Tabletop: the pallet is short and the device just reconnected

Pick task expects 100. The pallet has 80. The operator scanned before RF dropped; the screen now reconnects.

QUESTION 1

What must the operator NOT do?

QUESTION 2

What live facts must be refreshed?

QUESTION 3

What status is justified now?

QUESTION 4

Who owns correction and replanning?

Stop → refresh live pick + pallet → recount/verify → Hold if disposition unknown → log + supervisor → correct stock → replan.

Confidence comes from doing it once with your own examples

OPERATOR

Sign-in + warehouse
Put-Away · Pick · Move ·
Count
Stop rule + offline recovery

CLERK

Receipt + labels
Master-data correction
Status with reason

MANAGER

Shift control
Executable release
Exception + count review
Safe handoff

Your reference set after today
